Prof. Christian Schindelhauer

Organization

- ▶ I. Data and voice communication in IP networks
- ▶ II. Security issues in networking
- ▶ **III. Digital telephony networks and voice over IP**

Plan

- ▶ Voice over IP and other multimedia applications demand more bandwidth and realtime
- ▶ Introduction of special multimedia protocols
 - RTP (Real Time Transport Protocol)
 - RTCP (RTP Control Protocol)
 - RSVP (Resource Reservation Protocol)
- ▶ Problems of RSVP and multimedia challenges
- ▶ Bandwidth management and Quality of Services
- ▶ Provide QoS control in IP networks, i.e., going beyond best effort to provide some assurance for QoS
- ▶ Later on switch to Internet telephony, introduction to SIP and H.323.

Real Time Services

- ▶ Requirements toward networks for real-time audio and video at least
 - short delay (delay is composed from several parameters)
 - enough bandwidth: normally available in backbone networks
- ▶ But more problematic the (private) end user over low bandwidth connections
- ▶ During maturing of the Internet bandwidth was often scarce and expensive
 - many solutions to bandwidth management addressed the whole end-to-end system connection
 - but most concepts (e.g. the ToS flag in IP header) are not really used
- ▶ By now: It is often cheaper to add bandwidth than operating sophisticated bandwidth management
- ▶ But there are scenarios where quality of service (QoS) may improve the whole networks usability ...

Requirements Towards Network

- ▶ Voice over IP and Quality of Service:
- ▶ Major challenges: delay and delay variation (jitter)
 - Delay jitter is the variability of source-to-destination delays of packets within the same packet stream
 - Voice applications are usually interactive
 - Delay requirement for a telephone system:
150ms-250ms
- ▶ The group of Schneider identified the sources of delay in a voice over IP system:
 - OS delay: 10s-100s milliseconds (digitization of data, compression and inter software data handling) ...

Requirements Towards Network

- ▶ Source jitter:
 - Network: network conditions vary at different times.
 - Non-real time OS: samples processed at different time
- ▶ Jitter control - buffering at the destination – task of the application used
- ▶ QoS parameters which should be taken into account:
 - Accuracy, latency
 - Jitter and codec quality
- ▶ Depending on codec used a data stream of e.g. ~80kbit/s is generated for each direction (64kbit/s of ISDN PCM plus IP and UDP header)

Real Time Transport Protocol (RTP)

- ▶ Introduction of a special multimedia protocol
- ▶ Video and audio streaming
- ▶ Defined in RFC 1889, RFC 3550.
- ▶ Used for transporting common formats such as PCM and GSM for sound, and MPEG1 and MPEG2 for video
- ▶ RTP can be viewed as a sublayer of the transport layer
- ▶ Usually on top of UDP
 - 8byte header (faster transfer)
 - No setup overhead like with TCP session
 - no explicit connection handling (left to protocols like SIP) – faster

RTP – Packet Header

- ▶ RTP packet header
 - Payload type (7 bits): the type of audio/video encoding
 - Sequence number (16 bits)
 - Time stamp (32 bits): used for jitter removal - derived from a sampling clock at the sender
 - Synchronization Source Identifier (SSRC) (32 bits): identify the source of the RTP stream
 - It is not the IP address of the sender (would violate the layering) but a number that the source assigns randomly when the new stream is started

RTP Header

RTP – Header in Wireshark

The screenshot shows the Wireshark interface with a packet capture of RTP traffic. The packet list pane at the top shows several packets, with packet 10 selected. The details pane below shows the expanded view of packet 10, which is an RTP packet. The details pane is organized into sections: Internet Protocol, User Datagram Protocol, and Real-Time Transport Protocol. The RTP section shows the version as RFC 1889 Version (2).

No.	Time	Source	Destination	Protocol	Info
8	11.097953	217.10.79.9	80.131.245.242	SIP/SDP	Status: 200 OK, with session description
9	11.143631	80.131.245.242	217.10.79.9	SIP	Request: ACK sip:8006489@82.83.167.231:5060
10	11.147533	80.131.245.242	217.10.79.9	RTP	Payload type=ITU-T G.723, SSRC=3945704391, Seq=18960, Time=3600952048
11	11.153584	80.131.245.242	217.10.79.9	RTP	Payload type=ITU-T G.723, SSRC=3945704391, Seq=18961, Time=3600952288
12	11.183547	80.131.245.242	217.10.79.9	RTP	Payload type=ITU-T G.723, SSRC=3945704391, Seq=18962, Time=3600952528
13	11.213549	80.131.245.242	217.10.79.9	RTP	Payload type=ITU-T G.723, SSRC=3945704391, Seq=18963, Time=3600952768
14	11.243628	80.131.245.242	217.10.79.9	RTP	Payload type=ITU-T G.723, SSRC=3945704391, Seq=18964, Time=3600953008

Details for packet 10:

- Internet Protocol, Src Addr: 80.131.245.242 (80.131.245.242), Dst Addr: 217.10.79.9 (217.10.79.9)
- User Datagram Protocol, Src Port: avt-profile-1 (5004), Dst Port: 40718 (40718)
 - Source port: avt-profile-1 (5004)
 - Destination port: 40718 (40718)
 - Length: 40
 - Checksum: 0x0000 (none)
- Real-Time Transport Protocol
 - 10.. = Version: RFC 1889 Version (2)

The hex dump at the bottom shows the raw bytes of the packet, with the first 40 bytes corresponding to the RTP header.

RTP

- ▶ At the sender, the application puts its audio/video data with an RTP header and sends into the UDP socket
- ▶ The application in the receiver extracts the audio/video data from the RTP packet
 - Uses the header fields of the RTP packet to properly decode and playback the audio/video data
- ▶ Helper protocol: RTCP (RTP Control Protocol)
- ▶ RTCP packets do not encapsulate audio/video data

RTCP

- ▶ RTCP packets sent periodically between sender and receivers to gather useful statistics
 - number of packets sent
 - number of packets lost
 - inter arrival jitter
- ▶ RTP and RTCP packets are distinguished from each other through the use of distinct port numbers

RTCP – header in wireshark

Resource Reservation Protocol (RSVP)

- ▶ RTP needs a bandwidth at least of the rate as packets are sent in each direction
 - Otherwise packet loss or delays will occur and decrease the quality of data stream
- ▶ A special protocol was developed to add service quality parameters to the packet orientated internet
 - RSVP - part of a larger effort to enhance the current Internet architecture with support for Quality of Service flows
 - RFC 2205
- ▶ RSVP requests will generally result in resources being reserved in each node along the data path
 - Resource we speak of is bandwidth (delay is much more complicated to “reserve” within IP networks)

RSVP

- ▶ Signaling protocol introduced to reserve bandwidth between a source and its corresponding destination
- ▶ Main features of RSVP are
 - Use of “soft state” in the routers
 - receiver-controlled reservation requests
 - flexible control over sharing of reservations
 - forwarding of subflows
 - the use of IP multicast for data distribution
- ▶ Source → Destination: RSVP path message
- ▶ Destination → Source: RSVP reserve message
- ▶ Nice try – but ...

RSVP – Problems

- ▶ Routers cannot not store state information about packets – often too slow
- ▶ Simpler technique: mark each packet with a simple flag indicating how to treat it
- ▶ Individual flows are classified into different traffic classes
- ▶ Each router sorts packets into queues via differentiated services (DS) flag
- ▶ Queues get different treatment (e.g. priority, share of bandwidth, probability of discard)

RSVP – Problems

- ▶ Result is coarsely predictable class of service for each “differentiated services” field value
- ▶ Cost of transmission varies by type of service
- ▶ Each traffic class is reserved a defined level of resources, e.g. buffer and bandwidth
- ▶ Different QoS guarantee policies can be applied in different traffic classes
 - When congestion occurs, packets in low priority traffic classes will be dropped first
 - The buffer and the bandwidth in a router for high priority traffic classes are more than low priority traffic classes
- ▶ More scalable than RSVP but cannot allocate resources precisely

Multimedia Challenges and Packet Classification

- ▶ Remember the packet filtering lectures two weeks ago – IP is a service not offering much QoS features out of itself
- ▶ Reconsidering packet filtering from traffic shaping point of view
- ▶ Most router implementations:
 - Use only First-Come-First-Serve (FCFS), which might generate suboptimal results
 - Imagine running several VoIP connections on a shared DSL line with P2P file sharing
 - Limited packet processing and transmission scheduling
- ▶ To mitigate impact of “best-effort” protocols, we can:
 - Use UDP to avoid TCP and its slow-start phase...
 - Buffer content at client and control playback to remedy jitter
 - Adapt compression level to available bandwidth

Multimedia Challenges – Solutions

- ▶ Just add more bandwidth and enhance caching capabilities (over-provisioning)!
- ▶ Need major change of the protocols:
 - Incorporate resource reservation (bandwidth, processing, buffering), and new scheduling policies
 - Set up service level agreements with applications, monitor and enforce the agreements, charge accordingly
- ▶ Need moderate changes (“Differentiated Services”):
 - Use two traffic classes for all packets and differentiate service accordingly
 - Charge based on class of packets
 - Network capacity is provided to ensure first class packets incur no significant delay at routers

Quality of Service (QoS) – intro

- ▶ Talked earlier on new protocols like RTP, RTCP and RSVP – concentrate now on bandwidth management
- ▶ IETF groups are working on proposals to provide QoS control in IP networks, e.g., going beyond best effort to provide some assurance for QoS
- ▶ Work in Progress includes RSVP, Differentiated Services, and Integrated Services
- ▶ Simple model for sharing and congestion studies:

Quality of Service (QoS) – Intro

- ▶ Consider a phone/video application at 1Mbit/s and an FTP application sharing a 1.5 Mbit/s link.
 - bursts of FTP can congest the router and cause multimedia packets to be dropped.
 - want to give priority to audio/video streams over FTP
- ▶ PRINCIPLE 1: Marking of packets is needed for router to distinguish between different classes; and new router policy to treat packets accordingly

Quality of Service (QoS) – Intro

- ▶ Applications misbehave (audio/video sends packets at a rate higher than 1Mbit/s assumed above)
- ▶ PRINCIPLE 2: provide protection (isolation) for one class from other classes
- ▶ Require Policing Mechanisms to ensure sources adhere to bandwidth requirements; Marking and Policing need to be done at the edges:

Quality of Service (QoS) – Intro

- ▶ Alternative to Marking and Policing: allocate a set portion of bandwidth to each application flow; can lead to inefficient use of bandwidth if one of the flows does not use its allocation
- ▶ PRINCIPLE 3: While providing isolation, it is desirable to use resources as efficiently as possible

Quality of Service (QoS) – Intro

- ▶ Cannot support traffic beyond link capacity
 - Two phone calls each requests 1 Mbit/s
- ▶ PRINCIPLE 4: Need a Call Admission Process; application flow declares its needs, network may block call if it cannot satisfy the needs

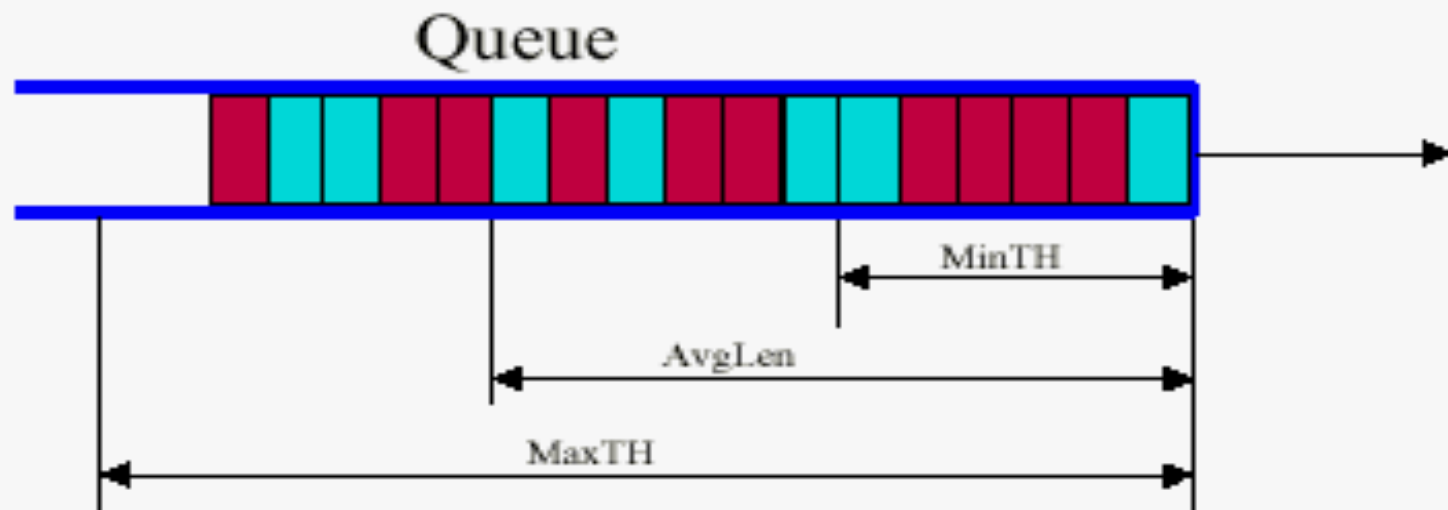

Quality of Service (QoS) – Packet Scheduling

- ▶ Scheduling: choosing the next packet for transmission
 - FIFO
 - Priority Queue
 - Round Robin
 - Weighted Fair Queuing

Quality of Service (QoS) – Packet Scheduling

Queue Management Using RED

✓ Random Early Detection

- monitor time-based average queue length (AvgLen) and drops arriving packets with increasing probability as AvgLen increases
- no action if $\text{AvgLen} < \text{MinTH}$ and all packets dropped if $\text{AvgLen} > \text{MaxTH}$
- Variants (e.g. WRED, FRED, RIO) increase fairness
- <http://www-nrg.ee.lbl.gov/floyd/red.html>

Quality of Service (QoS) – Packet Scheduling

- ▶ Policing mechanisms
 - (Long term) Average Rate
 - 100 packets per sec or 6000 packets per min??
 - * crucial aspect is the interval length
 - Peak Rate:
 - e.g., 6000 p p minute Avg and 1500 p p sec Peak
 - (Max.) Burst Size:
 - Max. number of packets sent consecutively, e.g. over a short period of time
 - Units of measurement
 - Packets versus bits

Quality of Service (QoS) – Packet Scheduling

- ▶ Token Bucket mechanism, provides a means for limiting input to specified Burst Size and Average Rate.
- ▶ Bucket can hold b tokens
- ▶ tokens are generated at a rate of r token/sec
 - unless bucket is full of tokens
- ▶ Over an interval of length t , the number of packets that are admitted is less than or equal to $(r t + b)$

Quality of Service (QoS) – Routing

- ▶ QoS routing – multiple restraints
- ▶ A request specifies the desired QoS requirements
 - e.g., BW, Delay, Jitter, packet loss, path reliability etc
- ▶ Two type of constraints:
 - Additive: e.g., delay
 - Maximum (or Minimum): e.g., Bandwidth
- ▶ Task
 - Find a (min cost) path which satisfies the constraints
 - if no feasible path found, reject the connection

Quality of Service (QoS) – Classification of Packets

- ▶ But often too complicated/impossible to define a path first, so use mechanism on “per-hop-behaviour” (PHB) - simply let routers decide on each hop what to do
 - Big advantage over protocols like RSVP – no state to be kept
- ▶ Give routers hints how to handle different packets
- ▶ Packet is marked in the Type of Service (TOS) in IPv4, and Traffic Class in IPv6
- ▶ 6 bits used for Differentiated Service Code Point (DSCP) and determine PHB that the packet will receive
- ▶ 2 bits are currently unused

Quality of Service (QoS) – Classification of Packets

- ▶ It may be desirable to limit traffic injection rate of some class; user declares traffic profile (e.g., rate and burst size); traffic is metered and shaped if non-conforming

Quality of Service (QoS) – Classification of Packets

- ▶ PHB result in a different observable (measurable) forwarding performance behavior
- ▶ PHB does not specify what mechanisms to use to ensure required PHB performance behavior
- ▶ Examples:
 - Class A gets $x\%$ of outgoing link bandwidth over time intervals of a specified length
 - Class A packets leave first before packets from class B

Quality of Service (QoS) – Classification of Packets

- ▶ PHBs under consideration:
 - Expedited Forwarding: departure rate of packets from a class equals or exceeds a specified rate (logical link with a minimum guaranteed rate)
 - Assured Forwarding: 4 classes, each guaranteed a minimum amount of bandwidth and buffering; each with three drop preference partitions
- ▶ But: AF and EF are not even in a standard track yet... research ongoing
- ▶ “Virtual Leased lines” and “Olympic” services are being discussed
- ▶ Impact of crossing multiple ASs and routers that are not DS-capable

Quality of Service (QoS) – Linux Implementation

- ▶ Practical implementations – deployed Linux QoS in an earlier practical session already, so tools should be familiar already
- ▶ Linux kernel includes several types of QoS features
 - Hierarchy token bucket (HTB)
 - Statistical fair queuing (SFQ)
 - Hierarchical Fair Service Curve Packet Scheduler
 - ...
- ▶ The iproute2 package is used to handle traffic classes (tc command)
- ▶ Linux packet filter is able to mark packets – so they could be handled later in QoS queues

Queueing Disciplines (qdisc) in Linux

- ▶ Queueing Discipline (qdisc) is an algorithm that manages the queue of a device, either incoming (ingress) or outgoing (egress).
- ▶ “tc” command in Linux
- ▶ Classless qdisc
 - shape traffic for an entire interface, without any subdivisions.
 - fifo_fast, Token Bucket Filter (TBF), Stochastic Fairness Queueing (SFQ)
- ▶ Classful qdisc
 - contains multiple classes having different priorities, different kinds of traffic can have different treatment.
 - PRIO , Class Based Queueing (CBQ), Hierarchical Token Bucket (HTB)

Classless Queueing

- ▶ pfifo_fast
 - First In, First Out. No packet receives special treatment.
 - The queue has 3 bands. Within each band, FIFO rules apply
- ▶ Token Bucket Filter (TBF)
 - Only passes packets arriving at a rate which is not exceeding the administratively set rate
 - But allow short bursts in excess of this rate
 - Have a buffer (bucket), constantly filled by tokens, at a specific rate (token rate)
 - Each arriving token collects one incoming data packet from the data queue and is then deleted from the bucket
 - The first choice if you just want to slow down an interface

Classless Queueing

- ▶ Stochastic Fairness Queueing (SFQ)
 - Traffic is divided into a pretty large number (limited number) of FIFO queues using hashing algorithm (hence stochastic)
 - One queue for one session
- ▶ Traffic is then sent in a round robin fashion, giving each session the chance to send data in turn

Classful queueing

- ▶ Contains multiple classes with different priorities, so different kinds of traffic can have different treatment.
- ▶ When the traffic enters a classful qdisc, it needs to be classified according to the 'filters'.
- ▶ PRIO (Priority queueing)
 - No shaping, only subdivides traffic based on filters
 - When a packet is enqueued to the PRIO qdisc, a class is chosen based on the filters
 - Very useful in case you want to prioritize certain kinds of traffic, without using only TOS-flags but using all the power of the tc filters

Classful Queuing

- ▶ Class Based Queuing (CBQ)
 - The most complex qdisc available
 - Implement shaping by measuring effective idle time, to make sure that the link is idle just long enough to bring down the real bandwidth to the configured rate
 - Subdivides traffic based on filters
 - When sending out a packet, uses a weighted round robin process ('WRR'), beginning with the lower-numbered priority classes

Classful Queuing

- ▶ Hierarchical Token Bucket (HTB)
- ▶ CBQ is complex and does not seem optimized for many typical situations
- ▶ HTB is well suited for setups where
 - you have a fixed amount of bandwidth
 - you want to divide the bandwidth for different traffics and give each traffic a guaranteed bandwidth
 - and specify how much bandwidth can be borrowed
- ▶ HTB works just like CBQ but does not resort to idle time calculations to shape
 - Instead, it is a classful Token Bucket Filter (hence the name :-))

Quality of Service (QoS) – Conclusion

- ▶ In most cases bandwidth (and IP first-come-first served) suffices
 - But you may have to connect a flatsharing community of students over a single DSL line
 - Provide Internet services for a student dormitory over a WLAN link with limited capacity
- ▶ Congested lines may render the whole service unusable
 - SSH gets unbearable delays, Mail download via POP or IMAP takes hours
 - Even filesharing does not work – ACK to downloaded packets have to wait to long ...
- ▶ That way you might solve a range of bandwidth related problems without the need to upgrade the connection
- ▶ Nevertheless at corporate level it is often cheaper just to add bandwidth than starting a sophisticated QoS management on switch and IP level
