Holes and Dense Areas

Size of Holes

Theorem

- If n elements are randomly inserted into an array [0,1[then with constant probability there is a "hole" of size $\Omega(\log n/n)$, i.e. an interval without elements.

Proof

- Consider an interval of size log n / (4n)
- The chance not to hit such an interval is (1-log n/(4n))
- The chance that n elements do not hit this interval is

$$\left(1 - \frac{\log n}{4n}\right)^n = \left(1 - \frac{\log n}{4n}\right)^{\frac{4n}{\log n} \frac{\log n}{4}} \ge \left(\frac{1}{4}\right)^{\frac{1}{4} \log n} = \frac{1}{\sqrt{n}}$$

- The expected number of such intervals is more than 1.
- Hence the probability for such an interval is at least constant.

$$\left| \frac{1}{4} \right|^{\frac{1}{4} \cdot \log n} = 2^{\left(\frac{1}{4} \cdot \log n \right) \cdot \log \frac{1}{4}}$$

$$= 2^{\left(\frac{1}{4} \right) \cdot \log n}$$

$$= n$$

Dense Spots

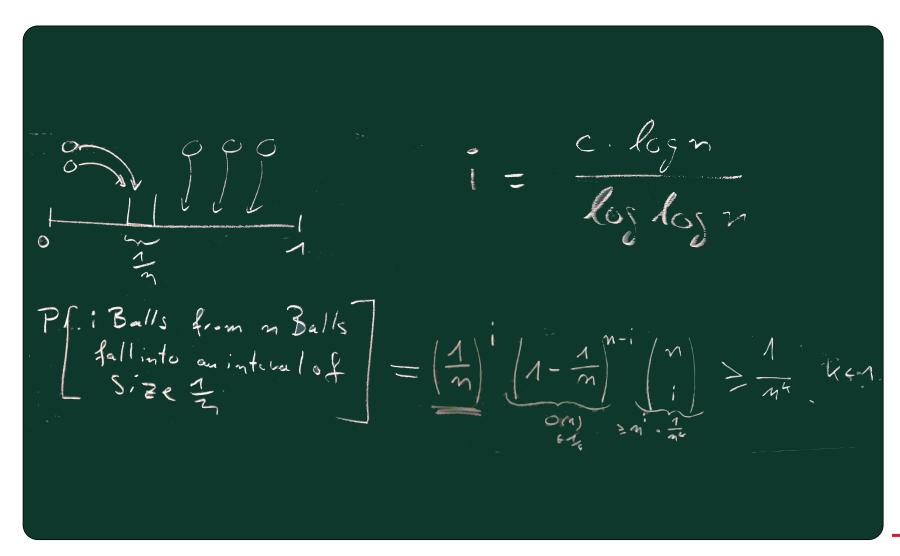

Theorem

If n elements are randomly inserted into an array [0,1 [then with constant probability there is a dense interval of length 1/n with at least Ω(log n/ (log log n)) elements.

Proof

- The probability to place exactly i elements in to such an interval is $\left(\frac{1}{n}\right)^i \left(1-\frac{1}{n}\right)^{n-i} \binom{n}{i}$
- for i = c log n / (log log n) this probability is at least 1/ n^k for an appropriately chosen c and k<1
- Then the expected number of intervals is at least 1

$$\frac{1}{4} \leq \left(1 - \frac{1}{m}\right)^{m} \leq \frac{1}{e}$$

$$\left(1 - \frac{1}{m}\right)^{n-1} = \left(1 - \frac{1}{m}\right)^{n}$$

$$\geq \left(\frac{1}{4}\right)^{1 - \frac{1}{m}}$$

$$\geq \frac{1}{4}$$

$$\begin{pmatrix}
n \\
i
\end{pmatrix} = \frac{n!}{i! (n-i)!} = \frac{n \cdot (i-n) \cdot (n-2) \cdot (n-i-n)}{i!}$$

$$\geq \frac{m \cdot m-1 \cdot m-2}{m} \cdot \frac{m-i+1}{m}$$

$$\geq (1-\frac{i-n}{m})^{m-i} \cdot \frac{n!}{i!}$$

$$\geq (1-\frac{i-n}{m})^{m-i} \cdot \frac{n!}{i!}$$

$$\geq (\frac{1}{4})^{(1-n)} = \frac{1}{2}$$

$$\frac{1}{2} = \frac{1}{1 - 1} \cdot \frac{1}{2} \cdot$$

Averaging Effect

Theorem

- If Θ (n log n) elements are randomly inserted into an array [0,1[then with high probability in every interval of length 1/n there are Θ (log n) elements.

Excursion

- Markov-Inequality
 - For random variable X>0 with E[X]>0:

$$\mathbf{P}[X \ge k \cdot \mathbf{E}[X]] \le \frac{1}{k}$$

Chebyshev

$$\mathbf{P}[|X - \mathbf{E}[X]| \ge k] \le \frac{\mathbf{V}[X]}{k^2}$$

$$\mathbf{V}[X] = \mathbf{E}[X^2] - \mathbf{E}[X]^2$$

Stronger bound: Chernoff

Chernoff-Bound

Theorem Chernoff Bound

- Let x₁,...,x_n independent Bernoulli experiments with
 - $P[x_i = 1] = p$
 - $P[x_i = 0] = 1-p$
- Let

$$S_n = \sum_{i=1}^n x_i$$

- Then for all c>0

$$\mathbf{P}[S_n \ge (1+c) \cdot \mathbf{E}[S_n]] \le e^{-\frac{1}{3}\min\{c,c^2\}pn}$$

- For 0≤c≤1

$$\mathbf{P}[S_n \le (1-c) \cdot \mathbf{E}[S_n]] \le e^{-\frac{1}{2}c^2pn}$$

We show

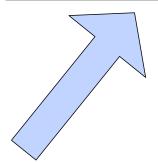

$$P[S_n \ge (1+c)\mathbf{E}[S_n]] \le e^{-\frac{\min\{c,c^2\}}{3}pn}$$

• Für t>0:

$$P[S_n \ge (1+c)pn] = P[e^{tS_n} \ge e^{t(1+c)pn}]$$

$$k = e^{t(1+c)pn} / E[e^{t \cdot S_n}]$$

$$\frac{1}{k} \le e^{-\frac{\min\{c,c^2\}}{3}pn}$$

Markov yields:

$$P\left[e^{tS_n} \ge k\mathbf{E}\left[e^{tS_n}\right]\right] \le \frac{1}{k}$$

To do: Choose t appropriately

We show

$$\frac{1}{k} \le e^{-\frac{\min\{c,c^2\}}{3}pn}$$

where $k = e^{t(1+c)pn}/E[e^{t\cdot S_n}]$

Independence of random variables x_i

Next we show:

$$\mathbf{E}[e^{tS_n}] = \mathbf{E}\left[e^{t\sum_{i=1}^n x_i}\right]$$

$$= \mathbf{E}\left[\prod_{i=1}^n e^{tx_i}\right]$$

$$= \prod_{i=1}^n \mathbf{E}\left[e^{tx_i}\right]$$

$$= \prod_{i=1}^n (e^0(1-p) + e^tp)$$

$$= (1-p+e^tp)^n$$

$$= (1+(e^t-1)p)^n$$

$$e^{-t(1+c)pn} \cdot (1+p(e^t-1))^n \le e^{-\frac{\min\{c,c^2\}}{3}pn}$$

Show:

$$e^{-t(1+c)pn} \cdot (1+p(e^t-1))^n \le e^{-\frac{\min\{c,c^2\}}{3}pn}$$

where: $t = \ln(1+c) > 0$

$$e^{-t(1+c)pn} \cdot (1+p(e^t-1))^n \leq e^{-t(1+c)pn} \cdot e^{pn(e^t-1)}$$

$$= e^{-t(1+c)pn+pn(e^t-1)}$$

$$= e^{-(1+c)\ln(1+c)pn+cpn}$$

$$= e^{(c-(1+c)\ln(1+c))pn}$$

Next to show

$$(1+c)\ln(1+c) \ge c + \frac{1}{3}\min\{c, c^2\}$$

To show for c>1:

$$(1+c)\ln(1+c) \ge c + \frac{1}{3}c$$

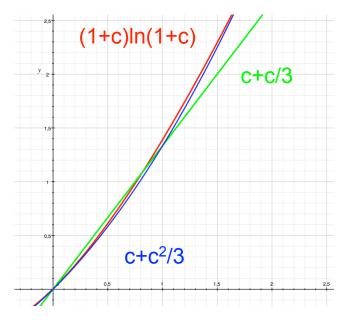

For c=1: 2 ln(2) > 4/3

Derivative:

- left side: ln(1+c)

- right side: 4/3

- For c>1 the left side is larger than the right side since
 - ln(1+c)>ln(2) > 4/3
- Hence the inequality is true for c>0.

To show for c< 1:

$$(1+c)\ln(1+c) \ge c + \frac{1}{3}c^2$$

For
$$x>0$$
:

$$\frac{d\ln(1+x)}{dx} = \frac{1}{1+x} = 1 - x + x^2 - x^3 + x^4 - \dots$$

Hence

$$\ln(1+x) = x - \frac{1}{2}x^2 + \frac{1}{3}x^3 - \frac{1}{4}x^4 + \dots$$

By multiplication

$$(1+x)\ln(1+x) = x + \left(1 - \frac{1}{2}\right)x^2 - \left(\frac{1}{2} - \frac{1}{3}\right)x^3 + \left(\frac{1}{3} - \frac{1}{4}\right)x^4 - \dots$$

Substitute (1+c) ln(1+c) which gives for $c \in (0,1)$:

$$(1+c)\ln(1+c) \ge c + \frac{1}{2}c^2 - \frac{1}{6}c^3 \ge c + \frac{1}{3}c^2$$

Chernoff-Bound

Theorem Chernoff Bound

- Let x₁,...,x_n independent Bernoulli experiments with
 - $P[x_i = 1] = p$
 - $P[x_i = 0] = 1-p$
- Let $S_n = \sum_{i=1}^n x_i$
- Then for all c>0

$$\mathbf{P}[S_n \ge (1+c) \cdot \mathbf{E}[S_n]] \le e^{-\frac{1}{3}\min\{c,c^2\}pn}$$

- For 0≤c≤1

$$\mathbf{P}[S_n \le (1-c) \cdot \mathbf{E}[S_n]] \le e^{-\frac{1}{2}c^2pn}$$

 $\mathbf{P}[S_n \le (1-c)\mathbf{E}[S_n]] \le e^{-\frac{c^2}{2}pn}.$ We show

$$e)\mathbf{E}[S_n]] \le e^{-\frac{c^2}{2}pn}.$$

▶ For t<0:
$$P[S_n \le (1-c)pn] = P[e^{tS_n} \ge e^{t(1-c)pn}]$$

$$\frac{1}{k} \le e^{-\frac{c^2}{2}pn}$$

$$k = e^{t(1-c)pn} / \mathbf{E}[e^{t \cdot S_n}]$$

Markov yields:

$$P\left[e^{tS_n} \ge k\mathbf{E}\left[e^{tS_n}\right]\right] \le \frac{1}{k}$$

To do: Choose t appropriately

We show

$$\frac{1}{k} \le e^{-\frac{c^2}{2}pn}$$

where

$$k = e^{t(1-c)pn} / \mathbf{E}[e^{t \cdot S_n}]$$

Independence of random variables x_i

Next we show:

$$e^{-t(1-c)pn} \cdot (1+p(e^t-1))^n \le e^{-\frac{c^2}{2}pn}$$

$$\mathbf{E}[e^{tS_n}] = \mathbf{E}\left[e^{t\sum_{i=1}^n x_i}\right]$$

$$= \mathbf{E} \left[\prod_{i=1}^{n} e^{tx_i} \right]$$

$$= \prod_{i=1}^{n} \mathbf{E} \left[e^{tx_i} \right]$$

$$= \prod_{i=1}^{n} (e^{0}(1-p) + e^{t}p)$$

$$= (1-p+e^tp)^n$$

$$= (1 + (e^t - 1)p)^n$$

We show

$$e^{-t(1-c)pn} \cdot (1+p(e^t-1))^n \le e^{-\frac{c^2}{2}pn}$$

where:

$$t = \ln(1 - c)$$

$$\begin{array}{lll} e^{-t(1-c)pn} \cdot (1+p(e^t-1))^n & \leq & e^{-t(1-c)pn} \cdot e^{pn(e^t-1)} \\ & = & e^{-t(1-c)pn+pn(e^t-1)} \\ & = & e^{-(1-c)\ln(1-c)pn-cpn} \end{array} \begin{tabular}{l} \mathbf{1+x} \leq \mathbf{e}^{\mathbf{x}} \\ & = & e^{-(1-c)\ln(1-c)pn-cpn} \\ \end{tabular}$$

Next to show
$$-c - (1-c) \ln(1-c) \le -\frac{1}{2}c^2$$

To prove:

$$-c - (1 - c)\ln(1 - c) \le -\frac{1}{2}c^2$$

For c=0 we have equality

Derivative of left side: ln(1-c)

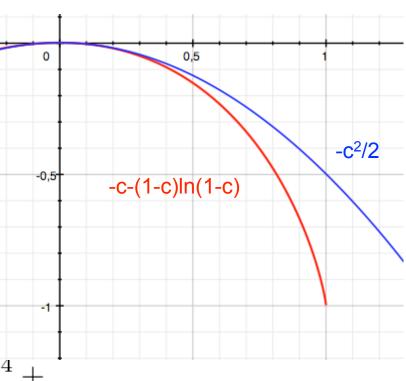

Derivative of right side: -c

Now

$$\ln(1+x) = x - \frac{1}{2}x^2 + \frac{1}{3}x^3 - \frac{1}{4}x^4 + \dots$$

This implies

$$\ln(1-c) = -c - \frac{1}{2}c^2 - \frac{1}{3}c^3 - \dots < -c$$

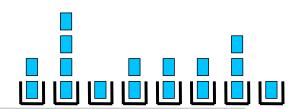

Proof ctd.

$$-c - (1-c)(-c-\frac{1}{2}c^2 - \frac{1}{3}c^3 - \frac{1}{3}c^3 - \frac{1}{3}c^4 - \frac{1}{3}c^5 - \frac{1}{3}c^2 - \frac{1}{3}c^3 - \frac{1}{3}c^4 - \frac{1}{3}c^5 - \frac{1}{3}c^2 - \frac{1}{3}c^3 - \frac{1}{3}c^4 - \frac{1}{3}c^5 - \frac{1}{3}c^2 - \frac{1}{3}c^3 - \frac{1}{3}c^4 - \frac{1}{3}c^5 - \frac{1}{3}c^5 - \frac{1}{3}c^2 - \frac{1}{3}c^3 - \frac{1}{3}c^4 - \frac{1}{3}c^5 - \frac{$$

Balls and Bins

Lemma

If m= k n ln n Balls are randomly placed in n bins:

- 1. Then for all c>k the probability that more than c ln n balls are in a bin is at most $O(n^{-c'})$ for a constant c'>0.
- 2. Then for all c<k the probability that less than c ln n balls are in a bin is at most $O(n^{-c^4})$ for a constant c'>0.

Proof:

Consider a bin and the Bernoulli experiment B(k n ln n,1/n) and expectation: $\mu = m/n = k \ln n$

$$P[X \ge c \ln n] = P[X \ge (1 + (c/k - 1))k \ln n]$$

$$\le e^{-\frac{1}{3}(c/k - 1)k \ln n} \le n^{-\frac{1}{3}(c - k)}$$

$$P[X \ge c \ln n] = P[X \ge (1 + (c/k - 1))k \ln n]$$

$$< e^{-\frac{1}{3}(c/k - 1)^2 k \ln n} < n^{-\frac{1}{3}(c-k)^2}$$

$$P[X \le c \ln n] = P[X \le (1 - (1 - c/k))k \ln n]$$

3. Case: c<k

$$\leq e^{-\frac{1}{2}(1-c/k)^2k\ln n} \leq n^{-\frac{1}{2}(k-c)^2/k}$$
